Note We discuss some important and common image-editing programs in depth in the next two sections, but for many of these tools you can also find tutorials on the Web. We've included the basics of the programs covered here to help give you a sense of what they do. # Align, Straighten, and Rotate Almost every photographer has at some time taken photos with a camera that's not level. This can be extremely frustrating, because the software that's developed to help people fix things like this is called `_image alignment_`. An image alignment tool helps you find the exact orientation that you need. The `_rotation tools_` are different from the normal tools you use in Photoshop. While you can rotate images any way you want by using the rotate tool in Photoshop, rotating them in a particular direction from the original image is called a `_clockwise_ _rotate_` or `_CW_ _rotate_`. The same rotation action can be accomplished using the tool by pressing the Tab key five times, or it can be done automatically by using the `_Rotate_ _Tool_` command (Ctrl+R). You can see the Rotation tool in Figure 10-15. Figure 10-15. Use the camera's 90-degree shift (CW or +90°) feature to create vertical images, where the top of the image is to the right. If you inadvertently shoot a landscape (a

This invention relates to an improved method for the treatment of waste waters containing organic solids with organic biodegradable solvents, particularly waste waters generated by the operation of pulp mills. In the operation of pulp mills the washed or unwashed chips and pulp slurry are removed from the digester and are treated with a physical solvent. The dewatering of the chips and pulp slurry usually is performed by a mechanical centrifugal action. The reclaimed pulp that results from such dewatering is usually brownish in color and has an objectionable odor. Most of the color and odor are due to the presence of the pulp fibers and the cooking chemicals, such as black liquor, that have been used to extract the lignin from the wood chips. The objectionable odor and color of the pulp slurry is considered to be objectionable by the pulp mill operator and it would be highly desirable to reduce or eliminate the objectionable odor and color without adversely affecting the quality of the pulp slurry. A number of methods have been suggested for reducing the objectionable odor and color of the pulp slurry. In U.S. Pat. No. 3,366,652, for instance, I describe a process for the treatment of cooked black liquor with chemicals that forms a precipitate containing an amine and an alkali metal hydroxide. The coagulated solids are removed from the pulp slurry by centrifugal action and then are washed with water. The diluted liquor is then sent to a neutralization stage and the carbonate of the amine is subjected to oxidation to form a more stable and odorless amine. Another method for removing objectionable compounds from pulp is that described in U.S. Pat. No. 3,908,668 wherein the pulp slurry is passed through a tubular bed of activated charcoal. The activated charcoal absorbs the objectionable compounds and contaminants in the pulp slurry and passes the treated pulp slurry to a decanter. Numerous organic solvents have been disclosed in the prior art for use in degreasing or bleaching the pulp. These solvents include alkyl and alkylene glycols and their esters (U.S. Pat. No. 3,839,089); alkyl C.sub.3 -C.sub.12 mono or dialkylene glycols (U.S. Pat. No. 3,267,738); alkyl or alkylene C.sub.6 -C.sub.6

Generally speaking, a computer system is comprised of, among other components, a processor, a display, a main storage device, a random access memory (RAM), and one or more optional input/output (I/O) devices. These devices, which provide connection points with and/or communication with outside devices (e.g., keyboards, a mouse, and a printer, etc.), are each electrically connected to the processor, or $\text{xe}2\text{x}80\text{x}9\text{cCPUxe}2\text{x}80\text{x}9\text{d}$ via one or more I/O busses. In the early days, many computer systems utilized a single, large main storage device. However, modern computer systems often utilize a hierarchy of devices to store data. This hierarchy may include any number of storage devices, including but not limited to a small, fast, expensive, local memory (such as a dynamic random access memory (DRAM)) and a larger, slower, less expensive mass storage device (such as a hard disk drive (HDD), a floppy disk drive (FDD), or an optical disk drive (ODD)). A computer system may be connected to a display device, such as a cathode ray tube (CRT) or a flat panel display (e.g., an active matrix liquid crystal display (AMLCD)). With modern computer systems, an operating system (OS) may enable the display device to be utilized as a graphical user interface (GUI) device. For example, a computer system may include a direct memory access (DMA) driver, which allows for data read or write operations to be sent directly to or from the RAM, without going through the CPU or I/O busses. For this reason, one or more additional I/O busses may be included in the computer system to facilitate communication between the I/O devices and the RAM. These I/O busses may be used for a variety of different purposes. Most graphics processors, which are often used for processing complex operations on the data being displayed to the user, are designed to perform these calculations on a significant amount of data at a time, and also to process data at a certain speed. Therefore, if a large amount of data has to be written to the graphic data base (GDB), it has to be written to the RAM, where it can be processed and displayed to the user in the desired order, and where it can be stored in the main storage device until it is needed. In order to facilitate the storage of
